

SQLite - Python

In this chapter, you will learn how to use SQLite in Python programs.

Installation

SQLite3 can be integrated with Python using `sqlite3` module, which was written by Gerhard Haring. It provides an SQL interface compliant with the DB-API 2.0 specification described by PEP 249. You do not need to install this module separately because it is shipped by default along with Python version 2.5.x onwards.

To use `sqlite3` module, you must first create a connection object that represents the database and then optionally you can create a cursor object, which will help you in executing all the SQL statements.

Python `sqlite3` module APIs

Following are important `sqlite3` module routines, which can suffice your requirement to work with SQLite database from your Python program. If you are looking for a more sophisticated application, then you can look into Python `sqlite3` module's official documentation.

Sr.No.	API & Description
1	<p>sqlite3.connect(database [,timeout ,other optional arguments])</p> <p>This API opens a connection to the SQLite database file. You can use ":memory:" to open a database connection to a database that resides in RAM instead of on disk. If database is opened successfully, it returns a connection object.</p> <p>When a database is accessed by multiple connections, and one of the processes modifies the database, the SQLite database is locked until that transaction is committed. The timeout parameter specifies how long the connection should wait for the lock to go away until raising an exception. The default for the timeout parameter is 5.0 (five seconds).</p> <p>If the given database name does not exist then this call will create the database. You can specify filename with the required path as well if you want to create a database anywhere else except in the current directory.</p>
2	<p>connection.cursor([cursorClass])</p> <p>This routine creates a cursor which will be used throughout of your database programming with Python. This method accepts a single optional parameter cursorClass. If supplied, this must be a custom cursor class that extends sqlite3.Cursor.</p>
3	<p>cursor.execute(sql [, optional parameters])</p> <p>This routine executes an SQL statement. The SQL statement may be parameterized (i. e. placeholders instead of SQL literals). The sqlite3 module supports two kinds of placeholders: question marks and named placeholders (named style).</p> <p>For example – cursor.execute("insert into people values (?, ?)", (who, age))</p>
4	<p>connection.execute(sql [, optional parameters])</p> <p>This routine is a shortcut of the above execute method provided by the cursor object and it creates an intermediate cursor object by calling the cursor method, then calls the cursor's execute method with the parameters given.</p>
5	<p>cursor.executemany(sql, seq_of_parameters)</p> <p>This routine executes an SQL command against all parameter sequences or mappings found in the sequence sql.</p>
6	

	<p>connection.executemany(sql[, parameters])</p> <p>This routine is a shortcut that creates an intermediate cursor object by calling the cursor method, then calls the cursor's executemany method with the parameters given.</p>
7	<p>cursor.executescript(sql_script)</p> <p>This routine executes multiple SQL statements at once provided in the form of script. It issues a COMMIT statement first, then executes the SQL script it gets as a parameter. All the SQL statements should be separated by a semi colon (;).</p>
8	<p>connection.executescript(sql_script)</p> <p>This routine is a shortcut that creates an intermediate cursor object by calling the cursor method, then calls the cursor's executescript method with the parameters given.</p>
9	<p>connection.total_changes()</p> <p>This routine returns the total number of database rows that have been modified, inserted, or deleted since the database connection was opened.</p>
10	<p>connection.commit()</p> <p>This method commits the current transaction. If you don't call this method, anything you did since the last call to commit() is not visible from other database connections.</p>
11	<p>connection.rollback()</p> <p>This method rolls back any changes to the database since the last call to commit().</p>
12	<p>connection.close()</p> <p>This method closes the database connection. Note that this does not automatically call commit(). If you just close your database connection without calling commit() first, your changes will be lost!</p>
13	<p>cursor.fetchone()</p> <p>This method fetches the next row of a query result set, returning a single sequence, or None when no more data is available.</p>
14	

	cursor.fetchmany([size = cursor.arraysize]) This routine fetches the next set of rows of a query result, returning a list. An empty list is returned when no more rows are available. The method tries to fetch as many rows as indicated by the size parameter.
15	cursor.fetchall() This routine fetches all (remaining) rows of a query result, returning a list. An empty list is returned when no rows are available.

Connect To Database

Following Python code shows how to connect to an existing database. If the database does not exist, then it will be created and finally a database object will be returned.

```
#!/usr/bin/python

import sqlite3

conn = sqlite3.connect('test.db')

print "Opened database successfully";
```

Here, you can also supply database name as the special name **:memory:** to create a database in RAM. Now, let's run the above program to create our database **test.db** in the current directory. You can change your path as per your requirement. Keep the above code in **sqlite.py** file and execute it as shown below. If the database is successfully created, then it will display the following message.

```
$chmod +x sqlite.py
$./sqlite.py
Open database successfully
```

Create a Table

Following Python program will be used to create a table in the previously created database.

```
#!/usr/bin/python

import sqlite3

conn = sqlite3.connect('test.db')
print "Opened database successfully";

conn.execute('''CREATE TABLE COMPANY
```

```

        (ID INT PRIMARY KEY         NOT NULL,
        NAME          TEXT          NOT NULL,
        AGE           INT           NOT NULL,
        ADDRESS       CHAR(50),
        SALARY        REAL);'''
print "Table created successfully";

conn.close()

```

When the above program is executed, it will create the COMPANY table in your **test.db** and it will display the following messages –

```

Opened database successfully
Table created successfully

```

INSERT Operation

Following Python program shows how to create records in the COMPANY table created in the above example.

```

#!/usr/bin/python

import sqlite3

conn = sqlite3.connect('test.db')
print "Opened database successfully";

conn.execute("INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) \
VALUES (1, 'Paul', 32, 'California', 20000.00 )");

conn.execute("INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) \
VALUES (2, 'Allen', 25, 'Texas', 15000.00 )");

conn.execute("INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) \
VALUES (3, 'Teddy', 23, 'Norway', 20000.00 )");

conn.execute("INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) \
VALUES (4, 'Mark', 25, 'Rich-Mond ', 65000.00 )");

conn.commit()
print "Records created successfully";
conn.close()

```

When the above program is executed, it will create the given records in the COMPANY table and it will display the following two lines –

```
Opened database successfully
Records created successfully
```

SELECT Operation

Following Python program shows how to fetch and display records from the COMPANY table created in the above example.

```
#!/usr/bin/python

import sqlite3

conn = sqlite3.connect('test.db')
print "Opened database successfully";

cursor = conn.execute("SELECT id, name, address, salary from COMPANY")
for row in cursor:
    print "ID = ", row[0]
    print "NAME = ", row[1]
    print "ADDRESS = ", row[2]
    print "SALARY = ", row[3], "\n"

print "Operation done successfully";
conn.close()
```

When the above program is executed, it will produce the following result.

```
Opened database successfully
ID = 1
NAME = Paul
ADDRESS = California
SALARY = 20000.0

ID = 2
NAME = Allen
ADDRESS = Texas
SALARY = 15000.0

ID = 3
NAME = Teddy
ADDRESS = Norway
SALARY = 20000.0

ID = 4
NAME = Mark
ADDRESS = Rich-Mond
```

```
SALARY = 65000.0
```

Operation done successfully

UPDATE Operation

Following Python code shows how to use UPDATE statement to update any record and then fetch and display the updated records from the COMPANY table.

```
#!/usr/bin/python

import sqlite3

conn = sqlite3.connect('test.db')
print "Opened database successfully";

conn.execute("UPDATE COMPANY set SALARY = 25000.00 where ID = 1")
conn.commit()
print "Total number of rows updated :", conn.total_changes

cursor = conn.execute("SELECT id, name, address, salary from COMPANY")
for row in cursor:
    print "ID = ", row[0]
    print "NAME = ", row[1]
    print "ADDRESS = ", row[2]
    print "SALARY = ", row[3], "\n"

print "Operation done successfully";
conn.close()
```

When the above program is executed, it will produce the following result.

```
Opened database successfully
Total number of rows updated : 1
ID = 1
NAME = Paul
ADDRESS = California
SALARY = 25000.0

ID = 2
NAME = Allen
ADDRESS = Texas
SALARY = 15000.0

ID = 3
NAME = Teddy
ADDRESS = Norway
```

```
SALARY = 20000.0
```

```
ID = 4
```

```
NAME = Mark
```

```
ADDRESS = Rich-Mond
```

```
SALARY = 65000.0
```

```
Operation done successfully
```

DELETE Operation

Following Python code shows how to use DELETE statement to delete any record and then fetch and display the remaining records from the COMPANY table.

```
#!/usr/bin/python
```

```
import sqlite3
```

```
conn = sqlite3.connect('test.db')
```

```
print "Opened database successfully";
```

```
conn.execute("DELETE from COMPANY where ID = 2;")
```

```
conn.commit()
```

```
print "Total number of rows deleted :", conn.total_changes
```

```
cursor = conn.execute("SELECT id, name, address, salary from COMPANY")
```

```
for row in cursor:
```

```
    print "ID = ", row[0]
```

```
    print "NAME = ", row[1]
```

```
    print "ADDRESS = ", row[2]
```

```
    print "SALARY = ", row[3], "\n"
```

```
print "Operation done successfully";
```

```
conn.close()
```

When the above program is executed, it will produce the following result.

```
Opened database successfully
```

```
Total number of rows deleted : 1
```

```
ID = 1
```

```
NAME = Paul
```

```
ADDRESS = California
```

```
SALARY = 20000.0
```

```
ID = 3
```

```
NAME = Teddy
```

```
ADDRESS = Norway
```

SALARY = 20000.0

ID = 4

NAME = Mark

ADDRESS = Rich-Mond

SALARY = 65000.0

Operation done successfully
